

Week 3 — Input & Strings → Mad Libs

Name: ____ Date: ____

`input()` asks and **waits**. Whatever comes back is a **string** — even "12" .

Today's words

Word	What it means
<code>input()</code>	asks a question, then waits (forever, if it has to) for an answer
f-string	a fill-in-the-blank sentence: <code>f"Hi, {name}!"</code> — braces get filled from the box
type	what KIND of thing a value is — text or number
<code>int()</code>	converts a string like "7" into the real number 7
concatenation	gluing strings with <code>+</code> : <code>"mad" + "libs"</code> → <code>"madlibs"</code>

1 • Be the computer 🤖

The user types **walrus** when asked. Write what each print line shows. (One line is missing its `f` — careful!)

```
animal = input("Animal? ")
print(f"A {animal} ate my homework!")
print("A {animal} ate my homework!")
```

Line 1: ____

Line 2: ____

2 • Adding or gluing? 🧩

Write what each one makes:

```
3 + 3          # → ____
"3" + "3"      # → ____
int("4") + 1   # → ____
"ha" + "ha"    # → ____
```

3 • Spot the bug 🐛

This program should print `Next year: 13` but it CRASHES on line 2. Circle the problem, then fix line 2 on the blank:

```
age = input("Age? ")          # user types: 12
print("Next year:", age + 1)
```

Fixed line 2: `print("Next year:", _____ )`

🧠 Brain teaser (optional — take it home)

Design your own Mad Libs! Write a 3–5 sentence story with **at least four blanks** (noun, verb, adjective, number — your choice). For each blank, write the exact question the computer should ask, like:

```
food = input("Give me a food: ")
```

Then write your story with the box names in {braces}. Bonus points if your number blank does MATH inside the story, like `{number * 100}`.

Bring it next week — the best one gets typed in and **run on the smartboard**, starring your words. Fame awaits.
